3. The dc value of  $V_{REF}$  applied to the receiving device is set to  $V_{TT}$
4. The values of  $I_{OH(dc)}$  and  $I_{OL(dc)}$  are based on the conditions given in Notes 1 and 2. They are used to test device drive current capability to ensure  $V_{IH}$  min plus a noise margin and  $V_{IL}$  max minus a noise margin are delivered to an SSTL\_18 receiver. The actual current values are derived by shifting the desired driver operating point (see Section 3.3) along a 21 ohm load line to define a convenient driver current for measurement.

### 3.3.3 OCD default characteristics

5. The absolute value of the slew rate as measured from DC to DC is equal to or greater than the slew rate as measured from AC to AC. This is guaranteed by design and characterization.
6. This represents the step size when the OCD is near 18 ohms at nominal conditions across all process corners/variations and represents only the DRAM uncertainty. A 0 ohm value(no calibration) can only be achieved if the OCD impedance is 18 ohms +/- 0.75 ohms under nominal conditions.

**Output Slew rate load:**

7. DRAM output slew rate specification applies to 400, 533 and 667 MT/s speed bins.
8. Timing skew due to DRAM output slew rate mis-match between DQS /  $\overline{\text{DQS}}$  and associated DQs is included in tDQSQ and tQHS specification.

## General notes, which may apply for all AC parameters

### 1. Slew Rate Measurement Levels

- Output slew rate for falling and rising edges is measured between  $V_{TT} - 250$  mV and  $V_{TT} + 250$  mV for single ended signals. For differential signals (e.g.  $\overline{DQS} - DQS$ ) output slew rate is measured between  $\overline{DQS} - DQS = -500$  mV and  $\overline{DQS} - DQS = +500$  mV. Output slew rate is guaranteed by design, but is not necessarily tested on each device.
- Input slew rate for single ended signals is measured from dc-level to ac-level: from  $V_{REF} - 125$  mV to  $V_{REF} + 250$  mV for rising edges and from  $V_{REF} + 125$  mV and  $V_{REF} - 250$  mV for falling edges. For differential signals (e.g.  $\overline{CK} - CK$ ) slew rate for rising edges is measured from  $\overline{CK} - CK = -250$  mV to  $\overline{CK} - CK = +500$  mV (250mV to -500 mV for falling edges).
- VID is the magnitude of the difference between the input voltage on  $\overline{CK}$  and the input voltage on  $\overline{CK}$ , or between  $\overline{DQS}$  and  $\overline{DQS}$  for differential strobe.

### 2. DDR2 SDRAM AC timing reference load

The following figure represents the timing reference load used in defining the relevant timing parameters of the part. It is not intended to be either a precise representation of the typical system environment nor a depiction of the actual load presented by a production tester. System designers will use IBIS or other simulation tools to correlate the timing reference load to a system environment. Manufacturers will correlate to their production test conditions (generally a coaxial transmission line terminated at the tester electronics).

The output timing reference voltage level for single ended signals is the crosspoint with  $V_{TT}$ . The output timing reference voltage level for differential signals is the crosspoint of the true (e.g.  $\overline{DQS}$ ) and the complement (e.g.  $\overline{DQS}$ ) signal.

### 3. DDR2 SDRAM output slew rate test load

Output slew rate is characterized under the test conditions as shown below.

#### 4. Differential data strobe

DDR2 SDRAM pin timings are specified for either single ended mode or differential mode depending on the setting of the EMRS "Enable DQS" mode bit; timing advantages of differential mode are realized in system design. The method by which the DDR2 SDRAM pin timings are measured is mode dependent. In single VREF. In differential mode, these timing relationships are measured relative to the crosspoint of DQS and its complement,  $\overline{\text{DQS}}$ . This distinction in timing methods is guaranteed by design and characterization. Note that when differential data strobe mode is disabled via the EMRS, the complementary pin,  $\overline{\text{DQS}}$ , must be tied externally to VSS through a 20 ohm to 10 K ohm resistor to insure proper operation.

5. AC timings are for linear signal transitions. See System Derating for other signal transitions.

6. These parameters guarantee device behavior, but they are not necessarily tested on each device. They may be guaranteed by device design or tester correlation.

7. All voltages referenced to VSS.

8. Tests for AC timing, IDD, and electrical (AC and DC) characteristics, may be conducted at nominal reference/supply voltage levels, but the related specifications and device operation are guaranteed for the full voltage range specified.

## Specific Notes for dedicated AC parameters

1. User can choose which active power down exit timing to use via MRS(bit 12). tXARD is expected to be used for fast active power down exit timing. tXARDS is expected to be used for slow active power down exit timing where a lower power value is defined by each vendor data sheet.
2. AL = Additive Latency
3. This is a minimum requirement. Minimum read to precharge timing is AL + BL/2 providing the tRTP and tRAS(min) have been satisfied.
4. A minimum of two clocks (2 \* tCK) is required irrespective of operating frequency
5. Timings are guaranteed with command/address input slew rate of 1.0 V/ns. See System Derating for other slew rate values.
6. Timings are guaranteed with data, mask, and (DQS/RDQS in singled ended mode) input slew rate of 1.0 V/ns. See System Derating for other slew rate values.
7. Timings are guaranteed with CK/CK differential slew rate of 2.0 V/ns. Timings are guaranteed for DQS signals with a differential slew rate of 2.0 V/ns in differential strobe mode and a slew rate of 1V/ns in single ended mode. See System Derating for other slew rate values.

1) For all input signals the total tDS(setup time) and tDH(hold time) required is calculated by adding the datasheet value to the derating value listed in Table x.

Setup(tDS) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VREF(dc) and the first crossing of Vih(ac)min. Setup(tDS) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VREF(dc) and the first crossing of Vil(ac)max. If the actual signal is always earlier than the nominal slew rate line between shaded 'VREF(dc) to ac region', use nominal slew rate for derating value(see Fig a.) If the actual signal is later than the nominal slew rate line anywhere between shaded 'VREF(dc) to ac region', the slew rate of a tangent line to the actual signal from the ac level to dc level is used for derating value(see Fig b.)

Hold(tDH) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of Vil(dc) max and the first crossing of VREF(dc). Hold (tDH) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of Vih(dc) min and the first crossing of VREF(dc). If the actual signal is earlier than the nominal slew rate line anywhere between shaded 'dc to VREF(dc) region', the slew rate of a tangent line to the actual signal from the dc level to VREF(dc) level is used for derating value(see Fig d.)

Although for slow slew rates the total setup time might be negative(i.e. a valid input signal will not have reached VIH/IL(ac) at the time of the rising clock transition) a valid input signal is still required to complete the transition and reach VIH/IL(ac).

For slew rate in between the values listed in table x, the derating valued may obtained by linear interpolation.

These values are typically not subject to production test. They are verified by design and characterization.

1) For all input signals the total tIS(setup time) and tIH(hold) time) required is calculated by adding the datasheet value to the derating value listed in above Table.

Setup(tIS) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of  $V_{REF}(dc)$  and the first crossing of  $V_{IH}(ac)_{min}$ . Setup(tIS) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of  $V_{REF}(dc)$  and the first crossing of  $V_{IL}(ac)_{max}$ . If the actual signal is always earlier than the nominal slew rate for line between shaded ' $V_{REF}(dc)$  to ac region', use nominal slew rate for derating value(see fig a.) If the actual signal is later than the nominal slew rate line anywhere between shaded ' $V_{REF}(dc)$  to ac region', the slew rate of a tangent line to the actual signal from the ac level to dc level is used for derating value(see Fig b.)

Hold(tIH) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of  $V_{IL}(dc)_{max}$  and the first crossing of  $V_{REF}(dc)$ . Hold(tIH) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of  $V_{REF}(dc)$ . If the actual signal is always later than the nominal slew rate line between shaded ' $dc$  to  $V_{REF}(dc)$  region', use nominal slew rate for derating value(see Fig.c) If the actual signal is earlier than the nominal slew rate line anywhere between shaded ' $dc$  to  $V_{REF}(dc)$  region', the slew rate of a tangent line to the actual signal from the dc level to  $V_{REF}(dc)$  level is used for derating value(see Fig d.)

Although for slow rates the total setup time might be negative(i.e. a valid input signal will not have reached  $V_{IH/IL}(ac)$  at the time of the rising clock transition) a valid input signal is still required to complete the transition and reach  $V_{IH/IL}(ac)$ .

For slew rates in between the values listed in table, the derating values may obtained by linear interpolation.

These values are typically not subject to production test. They are verified by design and characterization.

10. The maximum limit for this parameter is not a device limit. The device will operate with a greater value for this parameter, but system performance (bus turnaround) will degrade accordingly.

11. MIN (  $t_{CL}$ ,  $t_{CH}$  ) refers to the smaller of the actual clock low time and the actual clock high time as provided to the device (i.e. this value can be greater than the minimum specification limits for  $t_{CL}$  and  $t_{CH}$ ). For example,  $t_{CL}$  and  $t_{CH}$  are = 50% of the period, less the half period jitter (  $t_{JIT(HP)}$  ) of the clock source, and less the half period jitter due to crosstalk (  $t_{JIT(crosstalk)}$  ) into the clock traces.

12.  $t_{QH} = t_{HP} - t_{QHS}$ , where:

$t_{HP}$  = minimum half clock period for any given cycle and is defined by clock high or clock low (  $t_{CH}$ ,  $t_{CL}$  ).

$t_{QHS}$  accounts for:

- 1) The pulse duration distortion of on-chip clock circuits; and
- 2) The worst case push-out of DQS on one transition followed by the worst case pull-in of DQ on the next transition, both of which are, separately, due to data pin skew and output pattern effects, and p-channel to n-channel variation of the output drivers.

13.  $t_{DQSQ}$ : Consists of data pin skew and output pattern effects, and p-channel to n-channel variation of the output drivers as well as output slew rate mismatch between  $\overline{DQS}$  and associated DQ in any given cycle.

14.  $t_{DAL} = (nWR) + (t_{RP}/t_{CK})$ :

For each of the terms above, if not already an integer, round to the next highest integer.  $t_{CK}$  refers to the application clock period.  $nWR$  refers to the  $t_{WR}$  parameter stored in the MRS.

Example: For DDR533 at  $t_{CK} = 3.75$  ns with  $t_{WR}$  programmed to 4 clocks.  $t_{DAL} = 4 + (15 \text{ ns} / 3.75 \text{ ns})$   
clocks = 4 + (4)clocks = 8clocks.

15. The clock frequency is allowed to change during self-refresh mode or precharge power-down mode. In case of clock frequency change during precharge power-down, a specific procedure is required as described in section 2.9.

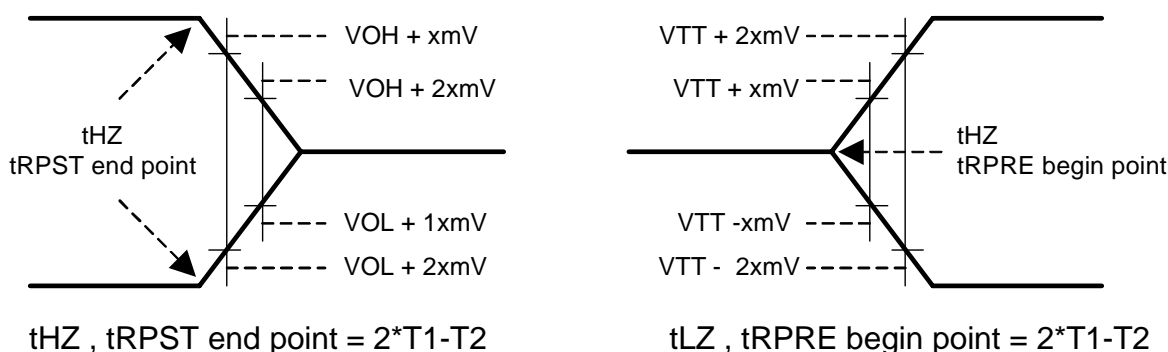

16. ODT turn on time min is when the device leaves high impedance and ODT resistance begins to turn on. ODT turn on time max is when the ODT resistance is fully on. Both are measured from  $t_{AOND}$ .

17. ODT turn off time min is when the device starts to turn off ODT resistance.

ODT turn off time max is when the bus is in high impedance. Both are measured from  $t_{AOFD}$ .

18.  $t_{HZ}$  and  $t_{LZ}$  transitions occur in the same access time as valid data transitions. These parameters are referenced to a specific voltage level which specifies when the device output is no longer driving ( $t_{HZ}$ ), or begins driving ( $t_{LZ}$ ). Below figure shows a method to calculate the point when device is no longer driving ( $t_{HZ}$ ), or begins driving ( $t_{LZ}$ ) by measuring the signal at two different voltages. The actual voltage measurement points are not critical as long as the calculation is consistent.

19. tRPST end point and tRPRE begin point are not referenced to a specific voltage level but specify when the device output is no longer driving (tRPST), or begins driving (tRPRE). Below figure shows a method to calculate these points when the device is no longer driving (tRPST), or begins driving (tRPRE). Below Figure shows a method to calculate these points when the device is no longer driving (tRPST), or begins driving (tRPRE) by measuring the signal at two different voltages. The actual voltage measurement points are not critical as long as the calculation is consistent.

20. Input waveform timing with differential data strobe enabled MR[bit10] = 0, is referenced from the input signal crossing at the  $V_{IH(ac)}$  level to the differential data strobe crosspoint for a rising signal, and from the input signal crossing at the  $V_{IL(ac)}$  level to the differential data strobe crosspoint for a falling signal applied to the device under test.

21. Input waveform timing with differential data strobe enabled MR[bit10] = 0, is referenced from the input signal crossing at the  $V_{IH(dc)}$  level to the differential data strobe crosspoint for a rising signal and  $V_{IL(dc)}$  to the differential data strobe crosspoint for a falling signal applied to the device under test.

22. Input waveform timing is referenced from the input signal crossing at the  $V_{IH(ac)}$  level for a rising signal and  $V_{IL(ac)}$  for a falling signal applied to the device under test.

23. Input waveform timing is referenced from the input signal crossing at the  $V_{IL(dc)}$  level for a rising signal and  $V_{IH(dc)}$  for a falling signal applied to the device under test.
